

Context-Free Path Querying with Single-Path Semantics by Matrix Multiplication

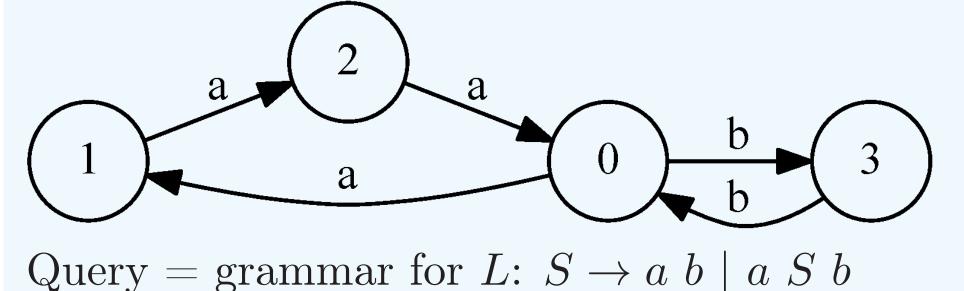

Rustam Azimov

 $Jet Brains\ Research,\ Saint\ Petersburg\ University,\ Russia\\ Rustam. Azimov@jetbrains.com$

Relational CFPQ

Find paths which satisfy constraints in form of a formal language $L = \{a^n b^n \mid n > 0\}$

Result: $\{(u, v) \mid \exists p \text{ from } u \text{ to } v : \text{word}(p) \in L\}$

Results

- We provide the matrix-based algorithm for CFPQ with single-path query semantics
- We provide several implementations of the CFPQ algorithms for both query semantics which use RedisGraph as graph storage
- We extend the dataset presented in [2] with new real-world and synthetic cases of CFPQ

Future Research

- Extend the matrix-based CFPQ algorithm to all-path query semantics
- Update the query results dynamically when data changes
- Include real-world cases from the area of static code analysis to the dataset
- Find new applications that required CFPQ

Matrix-Based Algorithm [1]

T is an adjacency matrix of the input graph The grammar is in the normal form

$$T_{ij} = \{ N \mid N \stackrel{*}{\Rightarrow} \omega, \omega - \text{path bw } i \text{ and } j \}$$

$$T_{ik} \times T_{kj} = \{ A \mid B \in T_{ik}, C \in T_{kj}, A \to BC \}$$

$$T^{(i)} = T^{(i-1)} \cup (T^{(i-1)} \times T^{(i-1)})$$

- Can be formulated in terms of boolean matrices multiplication
- Easy to run in parallel environments: GPUs, multithreaded CPUs, clusters

CFPQ with Single-Path Semantics

- We also need to provide one such path for all node pairs (u, v)
- Use PathIndex = (left, right, middle, height, length) as matrix elements
 - left, right the starting and the ending node of the path
 - middle the intermediate node of last path concatenation
 - height, length the height and the length of path
- Update the matrix operations to keep PathIndexes correct
- After the CFPQ algorithm we can extract the path stored
- The path extraction time is small and linear in the length of the path

New Implementations of CFPQ

- We use RedisGraph graph database as storage
- CPU-based implementations:
 - RG_CPU $_{rel}$ for the relation query semantics
 - $\mathbf{RG_CPU}_{path}$ for the single-path query semantics
- GPGPU-based implementations:
 - RG_CUSP_{rel} relational semantics, utilizes a CUSP library
 - RG_GPU $_{rel}$ relational semantics, uses low-latency on-chip shared memory for the hash table of each row of the result matrix
 - $\mathbf{RG_GPU}_{path}$ single-path semantics, operating over PathIndex

CFPQ Evaluation with Relational and Single-Path Query Semantics

Path length

- Time in seconds and memory is measured in megabytes
- Graph: real-world ontologies (RDFs), query: same-generation query
- Example of a grammar: $S \to scor S sco \mid tr S t \mid scor sco \mid tr t$
- GPGPUs utilization significantly increases the performance
- Implementations with sparse matrices significantly faster than others
- The cost of computing matrices with PathIndexes is not high
